

Studies on Character association for yield and yield attributing components in Sunflower (*Helianthus annuus L.*) germpalasms in coastal saline belts of West Bengal

S.S. Lakshman

Junior Breeder, All India Coordinated Research Project on Sunflower, RAKVK, Nimpith, SUNDARBANS, West Bengal, India

ABSTRACT

A study on genetic variability was made with different quantitative and yield attributing characters in sunflower (*Helianthus annuus L.*). One hundred and twenty five inbred lines of sunflower were selected for studying the character association both direct and indirect to assess the relationship among seed yield and its components. The trial was conducted in the Instructional Farm of Ramkrishna Ashram Krishi Vigyan Kendra, Nimpith on rabi-summer season of 2011-12. The analysis of variance revealed significant differences among the genotypes for all the characters under study. Observations were recorded on twelve different quantitative and yield attributing traits viz., days to 50% flowering, days to maturity, no. of leaves per plant, plant height (cm), head diameter (cm), 100-seed weight (g), no. of seeds per head, seed filling %, hull content (%), volume weight per 100 ml (g), oil content (%) and seed yield per plant (g) and (g). Hence simultaneous selection of these characters would contribute for the improvement of seed yield and oil yield per plant. The maximum positive association in relation to seed yield per plant were found with no. of seed per head, 100seed weight, head diameter and percentage of seed filling. The genetic influence of all the said four characters were more than 80% which signifies the importance of all these four characters in improving the seed yield in case of open pollinated population development as well as hybrid variety development programme.

Keywords: Sunflower, Yield, Character association, Selection indices.

I. INTRODUCTION

India is facing a shortage of edible oil in recent years. During 2009-10 India imported almost 8 million tonnes of vegetable oil which is almost 45 per cent of country's needs spending almost 25000 crores. Sunflower has maximum potential for bridging the gap in the demand and production of edible oil in the country. Its seeds contain high oil content ranging from 35 to 40% with some types yielding upto 50% (Skoric and Marinkovic, 1986). Oil yield is influenced by many plant traits like days to 50 %flowering, plant height, 100-seed weight, volume weight per 100 ml and oil content. Earlier Fick et al. (1974), Green (1980) and Joksimovic et al.

(1999) used simple correlation analysis to study the relationships between oil yield on one side and the other sunflower plant traits on the other side. In the present investigation, simple correlation between oil yield and its component characters was studied to identify the selection indices.

In the present investigation, 78 hybrids derived from crossing between 78 inbred lines and one CMS line 234 A by top cross fashion in sunflower (*Helianthus annuus L.*) were studied. They were raised in a randomized block design with two replication in the Oil seeds Farm, Centre for Plant Breeding and Nimpith during Summer 2010-11. In each replication, each entry was raised in 12.6 m² plot

adopting a spacing of 60 cm between the rows and 30 cm between plant to plant. Established agronomic practices were followed under irrigated condition. The data were recorded on ten randomly selected plants for the yield and yield contributing traits viz, days to 50% flowering, plant height, head diameter, 100-seed weight, volume weight per 100ml, oil content, seed yield per plant, oil yield per plant. The data collected were statistically analyzed for simple correlation.

Simple correlation coefficients among the oil yield and its component characters in sunflower are presented in Table 1. Oil yield was highly significant and positively correlated with seed yield per plant(0.97), plant height (0.49), head diameter (0.61), volume weight (0.29), 100-seed weight (0.49) and oil content (0.39). Similar results were reported by Chikkadevaiah et al. (2002), and Ramasubrahmanyam et al. (2002). The character days to 50% flowering had non-significant and positive association with oil yield. Association among yield components days to 50 per cent flowering had positive and significant correlation with plant height. Similar results were reported by Teklewold et al. (2000) and Vidhyavathi et al. (2005). Plant height had positive and significant correlated with head diameter, seed yield per plant. Similar reports were also made by Lakshminarayana et al., (2004) and Vidhyavathi et al. (2005). Head diameter had positive and significant per plant. Similar reports were also made by Moorthy (2004) and Manivannan et al. (2005). Volume weight had positive significant correlation with oil content and seed yield per plant. Similar results were reported by Vidhyavathi et al. (2005) and Manivannan et al. (2005). The character 100-seed weight had shown positively significant correlation with oil content and seed yield per plant.

The non significant association between days to 50% flowering and oil yield indicates that a breeder can

develop high oil yielding hybrids/varieties in early or late maturity group.

Hence considering the correlation analysis, characters namely plant height, head diameter, volume weight/100 ml, 100-seed weight, oil content and seed yield per plant are considered as important selection indices for oil yield improvement.
